

A network of TDOA sensors, even in the case where there are mobile stations, is more sensitive than an AOA network to the presence of areas served by only two stations and, *a fortiori*, only one station, within the broader coverage area of three or more stations. As the relative surface area of such poorly served areas increases, the effectiveness of a TDOA network and the possibility of automated geolocation therein declines sharply; yet, such automation is acknowledged to be a fundamental compelling motive for changing over to TDOA. This calls for more careful planning of TDOA sensor networks in comparison with networks of AOA DF stations, with the aim of minimizing such poorly served areas.
